Our purpose was to evaluate interfractional organ and patient movement during radiotherapy of prostate cancer and to calculate the necessary CTV to PTV margins. Fifty patients irradiated between 2009 and 2011 were included into the prospective study. The 2D-2D KV system combined with the intraprostatic fiducial marker were used for daily position verification. Based on the 8629 measurements of isocentre displacement an interfractional motion of pelvis and prostate was evaluated. The CTV to PTV margins were calculated. Margins of 0.7 cm (AP), 1 cm (SI) and 0.35 cm (LR) are necessary when only bony based IGRT is performed. Margins of 1.0 cm, 1.8 cm and 0.5 cm in AP, SI and LR directions respectively are necessary in case of no IGRT. There was no clinically relevant changes in patient/target mobility throughout the whole treatment. The IGRT is essential for state of art radiotherapy of prostate cancer. Necessary CTV to PTV margins are much bigger in case of no IGRT performed. Changing of margins size throughout regular treatment is not necessary.

*Key words: IGRT, prostate cancer, fiducial marker*

External beam radiotherapy is one of the main treatment modalities for patients with prostate cancer. Due to the positioning errors it is not possible to irradiate only the tumor volume. This obliges to use the additional margins around the target [1,2,3,4,5,6,7,8,9,10]. The CTV to PTV margins are not universal mainly due to variety of positioning verification systems and type of patient immobilization. There are still not many data on the set-up error changes, if daily image-guidance is performed. Image-guided radiotherapy (IGRT) is essential for state-of-art radiotherapy. IGRT becomes widespread, however the most advanced systems are unavailable in some radiation oncology centers particularly in developing countries [11,12,13,14,15,16,17].

IGRT based on 2D-2D KV system is simple and reliable in the routine clinical practice, especially when combined with radio-opaque markers implanted into the prostate gland [18,19,20]. It may provide simple and time-sparing patient position verification method, particularly for the centers which do not have the most advanced devices, dedicated for tumor movement tracking/correction.

If daily IGRT is not available, both prostate and patient displacements should be compensated with fair CTV to PTV margins. If everyday patient position verification is based only on bone structures, some margin should be used for internal movement (set-up error is theoretically eliminated). Intra-prostatic marker allows, indirectly, to image the position of the prostate and to correct the both patient and prostate displacements [21,22,23,24,25,26].

Interfraction motion is not a simple arithmetic sum of an internal error and a set-up error. In fact it is a vector of both random displacements represented by marker shift. Internal error is caused by prostate motion and set-up error is daily patient position fluctuation [27].

The aim of this prospective study is to evaluate an interfraction prostate motion and patient set-up variation during prostate cancer image guided radiotherapy using 2D-2D KV system in combination with radio-opaque fiducial markers. Based on that we would like to estimate the margins adequate for patients without any IGRT (internal + set-up margin) or those in whom KV IGRT is performed to pelvic bones only. We also would like to verify if there is a need to change the margins during treatment due to positioning errors throughout 38 subsequent fractions of radiotherapy.

Abbreviations: IGRT – Image-guided Radiotherapy; CTV – Clinical Target Volume; PTV – Planning Target Volume

**Patients and methods**

Fifty males (51-75 years old) with prostate cancer were included into the study and irradiated in our department of Radiotherapy between 2009 and 2011.

**Treatment planning.** The Golden Anchor™ markers were used for image-guidance procedures. The implantation was performed using a needle with diameter of 0.71 mm and transrectal ultrasonography guidance without anesthesia. Single marker was implanted. Computer tomography was done two weeks later. The planning was performed using 3D conformal or dynamic (intense-modulated or dynamic arc radiotherapy) techniques. Patients were irradiated with 2 Gy fraction dose to 76 Gy total dose for prostate (CTV) with added 0.6-1cm margin (PTV). Pelvic radiotherapy was planned to 44 Gy, if necessary. All patients were immobilized with pelvic thermoplastics masks with head-and-neck and knee support. The isocentre points were marked on the mask using lasers during simulation to positioning patient properly before the treatment. Every patient had to empty his bladder two hour prior to radiotherapy session and drink 500 ml of still water.

**Position verification.** The 2D-2D KV system was used for verification of the patient’s isocentre in the two orthogonal planes (0 and 270 degrees). KVs were compared to digitally reconstructed radiographs (DRR). KVs were taken before each fraction of radiotherapy. After DRR and KV images fusion an isocentre displacements in three directions were measured: anterior-posterior (AP), superior-inferior (SI) and left-right (LR). First measurement was completed for bone structures and then to the marker. The manual correction of table position was made in relation to the marker position.

Bone displacements were taken as a set-up error, while prostate markers displacements were taken as a combination (vector) of a set-up error and an internal prostate movement. Estimation from the differences between these two values was calculated separately for each direction and each fraction. It was the prostate displacement.

**Statistics.** We assumed 11400 measurements (50 patients, 38 fractions, 3 directions measured twice: bony structures and marker displacements). Due to technical problems (KV IGRT system breakdowns in random sessions) we achieved total of 8629 (75.7%) measurements.

The systematic ( $\Sigma$ ) and the random ( $\sigma$ ) errors were calculated separately for AP, SI, LR directions with formulas presented below:

$$\Sigma = \sqrt{\frac{1}{N-1} \sum_{j=1}^N (m_j - \bar{M})^2} \quad \sigma = \sqrt{\frac{1}{N} \sum_{j=1}^N (sd_j)^2}$$

where:  $sd_j$  is standard deviation of patient  $j$ ;  $\bar{M}$  is population mean systematic deviation;  $m_j$  is patient  $j$  mean systematic deviation;  $N$  is total number of patients.

The evaluation of the margins to receive PTV (assumed margins needed for 95% coverage) was based on the formula

proposed by van Herk. It included interfractional motion of the patient (set-up margin), the prostate gland (internal margin) or the combination of both (vector margin).

$$Margin = 2.5\Sigma + 0.7\sigma$$

The internal margin without set-up margin may be applied while image guidance based on bone structures only is performed. The vector margin compensates both organ and patient motion. Such margin is necessary when IGRT is not used.

To evaluate the rate (increase or decrease of isocentre displacements size) of positioning errors change throughout 38 subsequent fractions of radiotherapy a multilevel (hierarchical) modeling of the data with mixed effects was conducted. This was aimed to answer if patient/tumor movements tend to change and what is its trend during few weeks of external beam radiotherapy

The computation was done with R platform.

**Results**

The Gaussian distribution of measured displacements of isocentres showed that mean patient displacement (set-up error) was 0.19 cm (SD=0.27 cm), 0.11 cm (SD=0.82 cm) and -0.05 cm (SD=0.23 cm) for AP, SI and LR directions, respectively. The largest set-up error in SI direction was recorded.

The vector of both pelvis and prostate displacements (combination of set-up and internal errors) represented by marker was 0.16 (SD=0.40 cm), 0.09 cm (SD=0.82 cm) and -0.04 cm (SD=0.22 cm) for AP, SI and LR directions, respectively (Table 1).

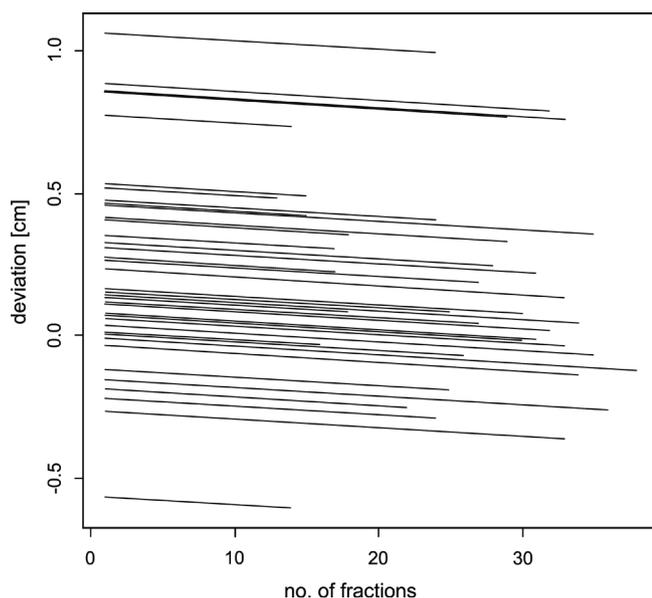

Prostate movement was calculated from the differences between the marker and bony structures displacements. The range of the internal error was the biggest in the SI direction (range=-1.6–2.2cm) and than in the AP direction (range=-2.1–1.1cm).

For the SI direction CTV to PTV margins estimation based on the van Herk’s formula were 1.76 cm for the set-up error, 0.97 cm for the internal error and 1.81 cm for the combination

**Table 1. Interfraction patient and prostate motion.**

	Direction	Mean [cm]	SD [cm]	Range [cm]
Set-up error	AP*	0.19	0.27	-0.6 – 1.1
	SI†	0.11	<b>0.82</b>	-2.9 – 3.0
	LR‡	-0.05	0.23	-1.4 – 1.4
Internal error	AP	-0.02	<b>0.32</b>	-2.1 – 1.1
	SI	0.01	<b>0.40</b>	-1.6 – 2.2
	LR	0.02	0.16	-0.9 – 0.8
Vector (combination of set-up and internal errors)	AP	0.16	0.40	-2.0 – 1.6
	SI	0.09	<b>0.82</b>	-2.7 – 2.9
	LR	-0.04	0.22	-1.3 – 1.3

\* anterior – posterior; †superior – inferior; ‡ left – right

**Figure 1.** Deviations of isocentre positioning error in AP direction throughout radiotherapy (each line represents one patient)

of both errors respectively. AP direction margin estimations were 0.66 cm for the set-up error, 0.73 cm for the internal error and 1 cm for the combination of both errors. The smallest margins were estimated for the LR direction. These were 0.48 cm, 0.35 cm and 0.51 cm for the set-up, internal and combination of both errors (Table 2).

A multilevel (hierarchical) modeling of the data with mixed effects showed statistically significant changes in the patient/prostate mobility in the AP direction throughout the treatment. These had low magnitude, which means little clinical relevance. The average reduction of isocentre deviations during daily radiotherapy was 0.003 cm per fraction ( $p = 0.0008$ ) It was around 0.1 cm throughout the whole treatment (Table 3).

**Table 2.** Systematic, random errors and margins to receive optimal PTV due to interfraction motion.

	Direction	$\Sigma$	$\sigma$	Margin [cm]
Set-up margin (SM)	AP*	0.22	0.17	0.66
	SI†	0.52	0.66	1.76
	LR‡	0.14	0.19	0.48
Internal margin (IM)§	AP	0.23	0.23	0.73
	SI	0.31	0.27	0.97
	LR	0.11	0.12	0.35
Vector margin (SM+IM)¶	AP	0.32	0.26	1.00
	SI	0.54	0.66	1.81
	LR	0.16	0.16	0.51

\*anterior-posterior; †superior-inferior; ‡ left-right; § necessary margins if KV IGRT alignment to bony structures enable; ¶ combination of set-up and internal margins, necessary margins if alignment only to centering points on thermoplastic mask enable without IGRT

Isocentre deviations in AP direction are shown on graph. The slope of each line is gradual, almost straight (Fig. 1).

## Discussion

This study shows that daily organ positioning is essential for appropriate radiotherapy of prostate cancer patients. However, image guided radiotherapy is not performed in all centers due to limited availability of such devices especially in developing countries. Radiotherapy based on KV's to bone pelvis is reasonable option for centers not equipped with the most advanced positioning verification systems. Intraprostatic marker implantation may reduce PTV significantly. The adequate CTV to PTV margins of 0.7 cm in AP, 1.0 cm in SI and 0.35 cm in LR seem adequate in case of pelvic bones verification without fiducial. Without any image-guidance, only thermoplastic mask immobilization, sufficient CTV to PTV margins should be 1 cm for AP direction, 1.8 cm for SI direction and 0.5 cm for LR direction. It makes irradiated volume larger and, of course, may increase treatment toxicity.

Our hypothesis that set-up and internal errors decrease throughout 38 fractions of radiotherapy was not confirmed. Although change in AP direction was statistically significant ( $p=0,0008$ ) it was clinically irrelevant. This means there is no need to change margins throughout regular treatment. In available scarce data decrease in interfractional error was found in patients with special diet. This was linked to less fecal gasses in rectum [28]. Set-up error analyses showed rather its increase, however it could be biased due to non-daily image guidance protocols [13,29,30,31].

Prostate cancer radiotherapy protocol variations or slightly different evaluation methods among radiotherapy centers may influence the results of various studies on positioning errors. Many publications describe portal verification [23,32,33,34,35,36,37]. Our group of prostate cancer patients treated with IGRT based on daily kVs and intraprostatic markers is the largest available.

Balter et al. published results of MV portal IGRT with radio-opaque markers in 10 prostate cancer patients. They proposed almost the same AP and LR direction margins as we did, however SI margin was over two-times smaller than ours. They suggested AP and LR directions as a natural prostate

**Table 3.** Isocentre deviations throughout 38 fractions of prostate cancer radiotherapy (multilevel modelling).

	Direction	Slope [cm]	SE	p-value
Bony structures	AP*	-0.0001	0.0006	0.8763
	SI†	0.0020	0.0023	0.3960
	LR‡	0.0005	0.0007	0.4413
Marker	AP	<b>-0.0030</b>	<b>0.0009</b>	<b>0.0008</b>
	SI	0.0031	0.0024	0.1991
	LR	0.0012	0.0006	0.0602

movement directions [33]. Other publication shows reduction of margins, if patient position adjustment was based on fiducial markers. When IGRT was not available, their LR margin would have to be two-times larger than ours. Moreover their SI margin was twice smaller for no IGRT situation, if compared to our SI margin. Margins in AP direction were comparable [23]. Enmark et al. reported daily verification based on three intraprostatic markers and ExactTrac Xray 6 D<sup>\*</sup> system [38]. When patient positioning was based on infrared skin markers only, AP and LR margins were similar to our results with patient alignment to isocenter drawn on plastic mask. If we compare our results to those published by Chen et al., again their SI direction margin was around two-times smaller than ours [39]. On the other hand they had LR direction margin around two-times larger than that proposed by us. In one of most recent publications by Langsenlehner et al. [40] AP and LR directions margins were larger than ours. SI direction margins were slightly smaller. So in our opinion isocenter points drawn on thermoplastic masks (our department practice) may have impact on larger set-up errors in SI direction. The mobility of the patients along SI direction is the largest in this type of immobilization system, however with plastic mask LR and AP displacements seem to be smaller. Moreover patient immobilization may decrease the risk of patient intrafractional motion (wriggling). Therefore, the advantages of such positioning seem to balance its disadvantages. The AP direction prostate movement is also linked with proximity of the rectum and bladder. It can be avoided with appropriate dietary instructions (e.g. non flatulent diet, fluid amount prior to irradiation, administration of an antifatulence medication).

The practice of IGRT was addressed in national surveys in 2010. Only 36.1% responses were received from 1600 radiation oncologist surveyed in United States of America. Although 93.5% of them used IGRT (82.3% when MV portals excluded), most of them used it rarely (less than 25% of patients) or infrequently (25% – 50% of patients). KV image-guidance was used by 57.7% of US radiation oncologists. From 50 radiation oncology centers in United Kingdom only 26 had at least one kV IGRT machine (23 centers used KVs). It was expected to increase this number to 43 by 2010. 115 from 139 Japanese major radiation oncology centers took part in national survey on use of new technologies in prostate cancer radiotherapy. 70 (60.9%) centers used IGRT, 54 of which used KVs for prostate radiotherapy image-guidance. 33 centers matched patient position to bones, 20 to prostate and 9 to implanted markers. Daily IGRT was carried out in 60 centers. IGRT with regular intervals was performed in nine. National Comprehensive Cancer Network guidelines allow daily IGRT only for prostate cancer patients since 2012, however it can be unachievable for many radiotherapy centres, particularly in developing countries [41,42,43].

Although IGRT is supposed to have its place in modern radiotherapy it seems that it is still not used widespread even in developed countries. This means that guidelines on CTV-PTV margins in such situations are still useful.

The use of daily IGRT eliminates most of errors associated with interfractional motion, but, naturally, does not allow the complete elimination of margins due to the presence of intrafraction motion, the risk of systematic errors in the process of treatment preparation, imaging, delineation errors etc.

There is no uniform and exact recommendation on prostate PTV, presently. Published margins range from 5 to 12 mm and more [15,22,27,40,44,45,46,47,48,49,50,51]. However, the CTV to PTV margins may be different in various situations based on policy of RT planning of treating centers. The results of this study demonstrate that use of IGRT minimize margins caused by interfraction motion. The most probable clinical impact is the possibility of decreasing the volume of irradiated rectum and bladder and radiotherapy toxicity reduction. We continue to collect and analyze these data.

In conclusion, the IGRT is essential for state of art radiotherapy of prostate cancer. Necessary CTV to PTV margins are much bigger in case if no IGRT is performed.

The additional CTV to PTV margin of 0.7 cm (AP), 1 cm (SI) and 0.35 cm (LR) is necessary when there is only bony based patient position correction possible. When there is no IGRT performed margins of 1.0 cm, 1.8 cm and 0.5 cm in AP, SI and LR directions respectively are necessary.

The variability of patient positioning errors in throughout 38 fractions of radiotherapy is clinically irrelevant. There is no need to change the size of margins defined while treatment plan is prepared.
